**ABSTRACT**

Naturalized British *Mimulus guttatus* Fischer ex DC. is diploid, \( n = 14 \). *M. moschatus* Dougl. ex Lindl. is also diploid, \( n = 16 \). Five hybrid clones derived from *M. guttatus* and species of the *M. luteus* L. complex (M. luteus, M. cupreus Dombrain and M. tigrinus hort.) had \( 2n = 45 \) and were sterile.

Three *Mimulus* species of American origin are naturalized in Britain. The North American *M. guttatus* Fischer ex DC. and *M. moschatus* Dougl. ex Lindl. and the South American *M. luteus* L. are part of the present-day British flora (Perring & Walters 1962, Warburg 1962, Roberts 1964). In addition, putative sterile hybrids of *M. guttatus* × *M. luteus* and *M. cupreus* × *M. guttatus* have been widely observed in Britain as escapes (Roberts 1964, 1968). *M. cupreus* Dombrain is a South American species which belongs to the *M. luteus* complex (Vickery 1969). It has been introduced to Britain as a garden plant but is doubtfully naturalized (Roberts 1968).

This note reports chromosome numbers and pairing of some naturalized British *Mimulus* populations. All chromosome observations were made on meiotic preparations of (1) fresh pollen-mother-cells (PMCs) stained in acetic orcein, or (2) PMCs which had been fixed in 1:3 acetic alcohol, stored in 70% alcohol and squashed in aceto-carmine. Vouchers for each population studied have been deposited in the University of Utah (UT) herbarium.

In North America, *M. guttatus* ranges from the Aleutian Islands to the Mexican state of Chihuahua and from the Pacific Coast inland to the Rocky Mountains. Over most of its range it is diploid \( (n = 14) \) but scattered tetraploid \( (n = 28) \) populations have evolved at the northwestern and southeastern limits of its range (McArthur et alii 1972). All six British populations reported here are diploid with \( n = 14 \) (Table 1).

The single population of *M. moschatus* examined has \( n = 16 \) (Table 1) as does western North American material (Mukherjee & Vickery 1961, Vickery & Tai 1970).

*M. luteus* occurs naturally along the flanks of the Andean Cordillera in Chile and Argentina. Although reported as widely distributed in Britain (Perring & Walters 1962), it is in fact quite rare. Many records of it are really records of hybrids between *M. luteus* and *M. guttatus* (Roberts 1964). *M. luteus* has aneuploid chromosome races of \( n = 30, 31 \) and 32 (Vickery 1969). Nineteenth-century European horticulturalists were active in developing showy garden plants using *M. luteus* and *M. cupreus* as stock (Grant 1924). Many races of these

1 Provided by R. H. Roberts.
3 Provided by R. H. Roberts. Studied by Roberts (1968).

two species are readily interfertile and produce fertile progeny (Roberts 1968, Vickery 1969). Some horticultural selections were developed with large, showy, yellow corollas blotched with red anthocyanin spots of various sizes and variously distributed; these were called *M. tigrinoides* hort. or *M. tigrinus* hort. (Grant 1924, Miller & Bailey 1929). These selections also have *n* = 31 ± 1 (Mukherjee & Vickery 1959, 1960; Mia et alii 1964) or 2*n* = c 64 (Brozek 1931, 1932) and are fertile. In Britain, however, selection has apparently been taken a step further. The horticultural selections, either by natural pollination or human design, were hybridized with *M. guttatus* producing sterile hybrids. I examined scores of garden plants from private and public gardens in Yorkshire, Lancashire, Cheshire, Durham, and Northumberland. Morphologically most of the plants
resembled the showy *M. tigrinus*, but some were more like *M. luteus*, *M. cupreus* or *M. guttatus*. None of these garden plants produced seed. Possibly the hybrids are so widely used because they do not seed themselves around the garden. It may also be, as suggested by Roberts (1964), that the hybrids are more winter-hardy than *M. luteus*. In any case, sterile hybrids of several morphological types are widely grown in Britain. They have spread and occur as naturalized clones along water-courses and in other wet places. The chromosome constitution of five of these clones was analyzed (Table 1). They all have \(2n = 45\). Analysis of 81 cells from four clones indicates a mean pairing association of \(0.26\, \text{m} + 11.12\, \text{n} + 21.98\, \text{l}\), with a range of \(0-3\, \text{m} + 6-15\, \text{n} + 14-33\, \text{l}\). These pairing results are essentially similar to those obtained by Mukherjee & Vickery (1962) and Mia & Vickery (1968) with greenhouse synthesized hybrids of *M. guttatus × M. luteus*. Most of the chromosome pairing in these hybrids has been attributed to the presence of a basic, 14 chromosome genome throughout most of section *Simiolus* Greene (Vickery 1966). Both *M. guttatus* and the *M. luteus* complex belong to this section.

The only previous chromosome count of naturalized British *Mimulus* was by Maude (1940). She reported a root-tip count of \(2n = 48\) for *M. langsdorffii* Donn (= *M. guttatus*), a chromosome number otherwise unrecorded for *M. guttatus*. This suggests that her specimen may have been a *M. guttatus*-like hybrid or a tetraploid *M. guttatus*. *Mimulus* chromosomes are small (0·5–3·0 \(\mu\)m) and often difficult to distinguish.

**ACKNOWLEDGMENTS**

Much of this research was carried out while I was an Agricultural Research Council Research Assistant in the Department of Agricultural Sciences, University of Leeds. I thank my supervisors there, Professor J. H. Western and Dr D. J. Harberd, for laboratory and greenhouse facilities. I also thank Mr K. Redshaw of the University’s Experimental Gardens for caring for *Mimulus* plants and sending vouchers and fixed buds to America. Mr R. H. Roberts of Bangor was generous in showing me some naturalized *Mimulus* hybrids and sharing plant material. The Society of the Sigma Xi provided travel funds which facilitated this study.
